## A Database road length models

We use the following functions to model the evolution of total mapped road length in each country (or region). In each case,  $y$  is the cumulative total street length in the database, while  $t$  represents the date, starting in March 2006. Except where specified in the case of Gompertz, all other parameters of each function are free parameters in the numerical optimization. Also, except for the linear function, which does not predict a saturation level nor date,  $y_{\max}$  represents the predicted actual road length, towards which the road length in the OSM database converges.

**Linear:** This function is zero until some time  $t_0$ , after which it represents simple linear growth.

$$y(t; t_0, m) = I(t > t_0)m[t - t_0]$$

Here, and below,  $I(\cdot)$  is an indicator function, giving value 1 when its argument is true and 0 otherwise.

**Logistic function:** This is the classic ‘‘sigmoid’’ curve.

$$y(t; k, y_{\max}) = y_{\max} \frac{1}{1 + e^{-k[t-t_0]}}$$

**Logistic with up to four jumps:** We introduce up to four jumps superposed on the logistic curve.

$$y(t; t_0, k, y_{\min}, y_{\max}, \{t_i\}, \{\delta_i\}) = y_{\min} + \sum_{i=1}^4 I(t > t_i) \delta_i + \frac{[y_{\max} - y_{\min} - \sum_{i=1}^4 \delta_i]}{1 + e^{-k[t-t_0]}}$$

Here  $i$  ranges from 1 to 4 and the  $t_i$  are dates on which the road network length underwent a discontinuous increase. We also allow for 1, 2, or 3 jumps, rather than 4, as separate specifications.

**Gompertz:** The Gompertz function is another sigmoid curve which allows for asymmetry between the concave and convex regions.

$$y(t, t_0, t_1; y_{\max}, b, c) = y_{\max} \exp\left(-b \exp\left(-c \frac{t - t_0}{t_1 - t_0}\right)\right)$$

where  $t_0$  and  $t_1$  are fixed to be the first and last times in the time series.

The best fit is almost always obtained through the sigmoid functions with jumps. The linear fit produces the lowest mean-square error for just 1 country (Estonia), and the Gompertz function for 19 countries. The remaining countries are fit with a sigmoid function with no jump (2 countries), one jump (41), two jumps (44), three jumps (58), four jumps (84), or one ramp (4).

Where the model suggests that completeness is greater than one (i.e., the asymptote lies slightly below the maximum observed value), we code completeness as 1.0. In 22 countries, the model estimated completeness to be greater than 1.05. These are: Syrian Arab Republic, Ghana, Afghanistan, Burkina Faso, Malawi, Yemen, Haiti, Montenegro, Swaziland, New Caledonia, Gambia, Timor-Leste, Martinique, Cabo Verde, Brunei Darussalam, Barbados, Virgin Islands (U.S.), Dominica, Saint Vincent and the Grenadines, Kiribati, Liechtenstein, and Holy See. These countries tend to have experienced relatively recent rapid growth in the road network, and thus the parametric fit is likely to be less reliable—highlighting the value of using two independent methods to estimate completeness.

## B Sensitivity check: the lengths of missing edges

We analyzed the length of existing vs missing edges formally for five randomly selected countries: Great Britain, Malta, Angola, French Guiana, and Djibouti. We compared the edge length of ways that existed in the OSM database on January 1, 2016, and compared that to a version of the OSM database from November 7, 2016. In both cases, we used the osm2po segmenter (osm2po.de) and restricted the database to the OSM tags described in the section ‘‘Saturation of contributions’’ of the main text. In each country, the average edge length became shorter over the  $\sim 10$ -month period, implying that missing ways are also shorter. This makes sense given that longer edges are easier to include when tracing aerial imagery, and are less likely to be overlooked. Specifically, the reduction in length was 1.6% (Great Britain), 0.7% (Malta), 18.1% (Angola), 7.1% (French Guiana), and 11.2% (Djibouti). Note that the reduction in edge length is not solely due to newly added roads being shorter, but also arises when an existing edge is split by a newly added intersecting street.

## C Table of estimated values

Country	Length		Fraction complete				
	Total (10 <sup>3</sup> km)	Per capita (m)	Best	Multilevel model	Parametric fits		
					Country-level	From sub- geography	From quintiles
World	40000		0.83	0.83 (0.81–0.84)	0.97 (Logistic+2J)	0.87	0.95

## I Data release

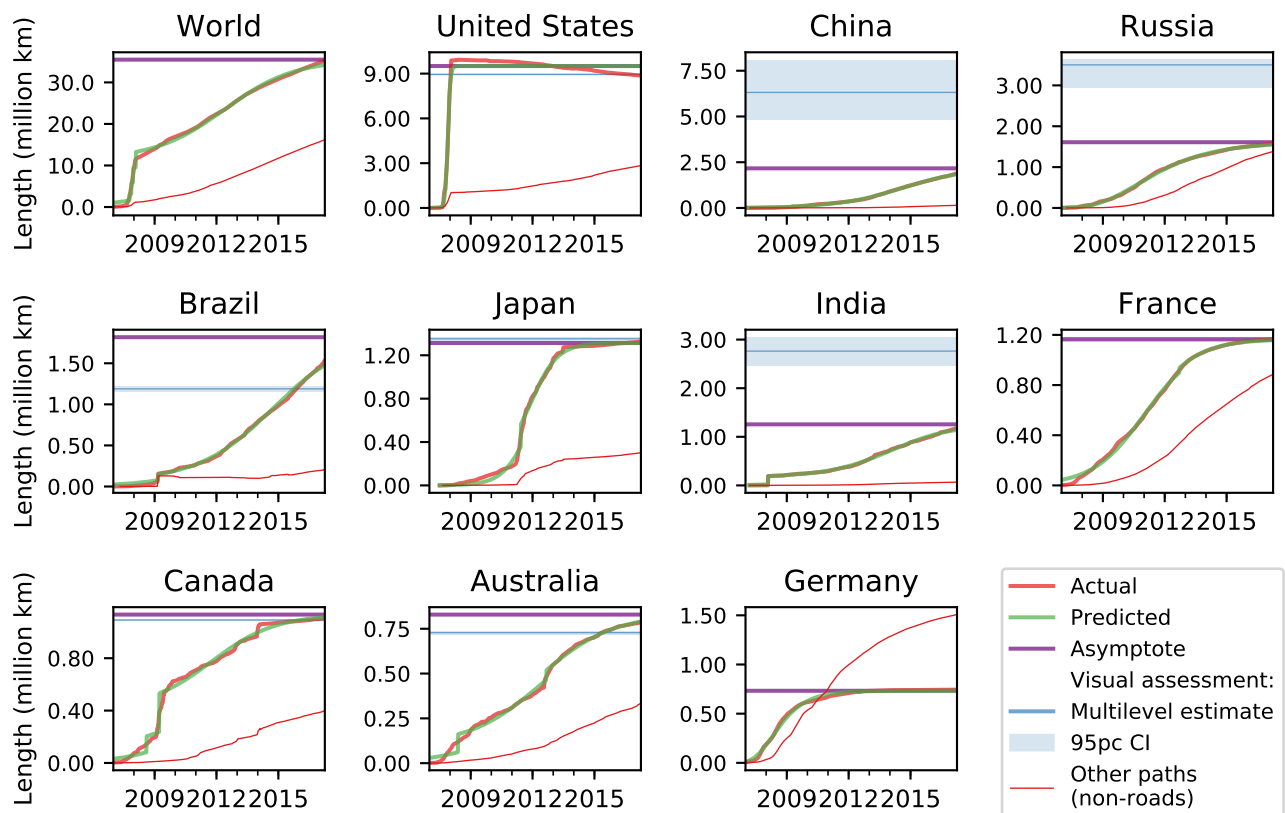

We provide both the data set corresponding to the published paper, and a 2017 update. Within each, three separate components are provided:

1. a compiled country-level dataset
2. the visual assessment data
3. the OpenStreetMap history, aggregated by density, national and sub-national boundaries.

These data are openly available at <https://alum.mit.edu/www/cpbl/publications/PLoS2017roads>

## J 2017 update

We updated our analysis to use the OSM contribution history up to May 2017. Using these updated data, both our methods find an 89% completion rate for roads, overall, planet-wide. Below are our fits corresponding to Figure 4 in the paper.

## K Open source Python code

Our code to reproduce the data and analysis is released under the GNU General Public License v3.0 as an open source project, permanently available at:

<https://alum.mit.edu/www/cpbl/publications/PLoS2017roads/osm-completeness>

A direct link to a description of the code is at:

<https://github.com/cpbl/osm-completeness/blob/master/README.md>

## **L Citation**

For any use of data or code, cite the original PLOS One paper:

Christopher Barrington-Leigh and Adam Millard-Ball, “The world’s user-generated road map is more than 80% complete,” *PLOS One*, doi:10.1371/journal.pone.0180698, August 2017.
