# FIELD-SWITCHING IN HOMOMORPHIC ENCRYPTION 

Craig Gentry
Shai Halevi
Chris Peikert
Nigel P. Smart

## HE Over Cyclotomic Rings

$\square$ Denote the field $K_{m}=Q\left(\zeta_{m}\right) \cong Q[X] /\left(\Phi_{m}(X)\right)$

- Its ring of integers is $R_{m}=Z\left(\zeta_{m}\right) \cong Z[X] /\left(\Phi_{m}(X)\right)$
$\square$ Mod- $q$ denoted $R_{m, q}=R_{m} / q R_{m} \cong Z_{q}[X] /\left(\Phi_{m}(X)\right)$
$\square$ "Native plaintext space" is $R_{m, 2}$
$\square$ Ciphertexts*, secret-keys are vectors over $R_{m, q}$
$\square \boldsymbol{C}$ wrt $\boldsymbol{S}$ encrypts $a$ if (for representatives in $R_{m}$ ) we have $\langle s, c\rangle=a \cdot \frac{q}{2}+e(\bmod q)^{*}$ for small $e$
- Decryption via $a:=\operatorname{MSB}(\langle s, c\rangle)^{*}$
$\square$ Using "appropriate" $Z$-bases of $R_{m, 2}, R_{m, q}$

## HE Over Cyclotomic Rings

$\square$ "Native plaintexts" encode vectors of values
$\square a \in R_{m, 2} \rightarrow\left(\alpha_{1} \ldots \alpha_{\ell}\right) \in G F\left(2^{d}\right)^{\ell}$ (more on that later)
$\square$ Homomorphic Operations
$\square$ Addition: $\boldsymbol{c} \boxplus \boldsymbol{c}^{\prime}$ encrypts $a+a^{\prime} \in R_{m, 2}$, encoding $\left(\alpha_{1}+\alpha_{1}^{\prime} \ldots \alpha_{\ell}+\alpha_{\ell}^{\prime}\right)$
$\square$ Multiplication: $\boldsymbol{c} \boxtimes \boldsymbol{c}^{\prime}$ encrypts $a \times a^{\prime} \in R_{m, 2}$, encoding $\left(\alpha_{1} \times \alpha_{1}^{\prime} \ldots \alpha_{\ell} \times \alpha_{\ell}^{\prime}\right)$
$\square$ Automorphism: $\boldsymbol{c}\left(X^{t}\right)$ encrypts $a\left(X^{t}\right) \in R_{m, 2}$, encoding some permutation of ( $\alpha_{1} \ldots \alpha_{\ell}$ )

- Relative to key $\boldsymbol{s}\left(X^{t}\right)$

## HE Over Cyclotomic Rings

$\square$ Also a key-switching operation
$\square$ For any two $\mathbf{s}, \mathbf{s}^{\prime} \in\left(R_{m, q}\right)^{2}$ we can publish a key-switching gadget $W\left[\boldsymbol{s} \rightarrow \boldsymbol{s}^{\prime}\right]$
$\square W$ used to translate valid $\mathbf{c}$ wrt $\mathbf{S}$ into $\mathbf{c}^{\prime}$ wrt $\mathbf{S}^{\prime}$
$\square \mathbf{c}, \mathbf{c}^{\prime}$ encrypt the same plaintext

$$
\langle\boldsymbol{s}, \boldsymbol{c}\rangle=\left\langle\boldsymbol{s}^{\prime}, \boldsymbol{c}^{\prime}\right\rangle+e(\bmod q)
$$

for some small $e$

## How Large are $m, q$ ?

$\square$ Ciphertexts are "noisy" (for security)
$\square$ noise grows during homomorphic computation
$\square$ Decryption error if noise grows larger than $q$
$\Rightarrow$ Must set $q$ "much larger" than initial noise
$\rightarrow$ Security relies on LWE-hardness with very large modulus/noise ratio
$\rightarrow$ Dimension ( $m$ ) must be large to get hardness
$\square$ Asymptotically $|q|=\operatorname{polylog}(k), m=\widetilde{\Omega}(k)$
$\square$ For realistic settings, $|q| \approx 1000, m>10000$

## Switching to Smaller m?

$\square$ As we compute, the noise grows
$\square$ Cipehrtexts have smaller modulus/noise ratio
$\square$ From a security perspective, it becomes permissible to switch to smaller values of $m$
$\square$ How to do this?
$\square$ Not even clear what outcome we want here:
$\square$ Have $\boldsymbol{c}$ wrt $\boldsymbol{S} \in\left(R_{m, q}\right)^{2}$, encrypting some $a \in R_{m, 2}$
$\square$ Want $\boldsymbol{c}^{\prime}$ wrt $\boldsymbol{s}^{\prime} \in\left(R_{m^{\prime}, q}\right)^{2}$ for $m^{\prime}<m$

- Encrypting $a^{\prime} \in R_{m^{\prime}, 2}$ ??

## Ring-Switching: The Goal

$\square$ We cannot get $a^{\prime}=a$ since $a^{\prime} \in R_{m^{\prime}, 2}, a \in R_{m, 2}$
$\square$ We want $a^{\prime}$ to be "related" to $a$
$\square a \in R_{m, 2}$ encodes $\left(\alpha_{1} \ldots \alpha_{\ell}\right) \in G F\left(2^{d}\right)^{\ell}$
$\square a^{\prime} \in R_{m^{\prime}, 2}$ encodes $\left(\alpha_{1}^{\prime} \ldots \alpha_{\ell^{\prime}}^{\prime}\right) \in G F\left(2^{d^{\prime}}\right)^{\ell^{\prime}}$
$\square$ May want $a^{\prime}$ to encode a subset of the $\alpha_{i}$ 's?

- E.g., the first $\ell^{\prime}$ of them
$\square$ Not always possible, only if $d^{\prime}=d$
$\square$ What relations between the $\alpha_{j}^{\prime}, \alpha_{i}$ 's are possible?

## Prior Work

$\square$ A limited ring-switching technique was described in [BGV'1 2]
$\square$ Only for $m=2^{n}, m^{\prime}=2^{n-1}$
$\square$ Transforms big-ring $\mathbf{c}$ into small-ring $\boldsymbol{c}_{\mathbf{1}}^{\prime}, \boldsymbol{c}_{\mathbf{2}}^{\prime}$
s.t. a (encrypted in $\mathbf{c}$ ) can be recovered from $a_{1}^{\prime}, a_{2}^{\prime}$ (encrypted in $\boldsymbol{c}_{\mathbf{1}}^{\prime}, \boldsymbol{c}_{\mathbf{2}}^{\prime}$ ).
$\square$ Used only for bootstrapping

## Our Transformation: Overview

$\square$ Work for any $m, m^{\prime}$ as long as $m^{\prime} \mid m$
$\square \mathbf{c}$ wrt $\mathbf{s} \in\left(R_{m, q}\right)^{2} \rightarrow \mathbf{c}^{\prime}$ wrt $\mathbf{s}^{\prime} \in\left(R_{m^{\prime}, q}\right)^{2}$
$\square \mathbf{c}, \mathbf{c}^{\prime}$ encrypt $a, a^{\prime}$, that encode vectors:
$\square \boldsymbol{c} \rightarrow\left(\alpha_{i}\right) \in G F\left(2^{d}\right)^{\ell}, \mathbf{c}^{\prime} \rightarrow\left(\alpha_{j}^{\prime}\right) \in G F\left(2^{d^{\prime}}\right)^{\ell^{\prime}}$

- Necessarily $d^{\prime} \mid d$, so $G F\left(2^{d^{\prime}}\right)$ a subfield of $G F\left(2^{d}\right)$
$\square$ Each $\alpha_{j}^{\prime}$ is a $G F\left(2^{d^{\prime}}\right)$-linear function of some $\alpha_{i}{ }^{\text {'s }}$
$\square$ We can choose the linear functions, but not the subset of $\alpha_{i}{ }^{\text {'s }}$ that correspond to each $\alpha_{j}^{\prime}$
$\square$ If $d^{\prime}=d$, can use projections (so $\alpha_{j}^{\prime}$ 's a subset of $\alpha_{i}$ 's)

## Our Transformation: Overview

Denote $K=K_{m}, R=R_{m}, K^{\prime}=K_{m^{\prime}}, R^{\prime}=R_{m^{\prime}}$

1. Key-switching to map $\boldsymbol{c}$ wrt $\boldsymbol{s} \rightarrow \boldsymbol{c}^{\prime \prime}$ wrt $\boldsymbol{s}^{\prime}$

- $\boldsymbol{s} \in R_{q}^{2}$ and $\boldsymbol{s}^{\prime} \in R_{q}^{\prime 2} \subset R_{q}^{2}$
- $\boldsymbol{c}^{\prime \prime}=\left(c_{0}^{\prime \prime}, c_{1}^{\prime \prime}\right)$ over the big field, wrt subfield key

2. Compute a small $r \in R_{q}$ that depends only on the desired linear functions
3. Apply the trace function, $c_{i}^{\prime}=\operatorname{Tr}_{K / K^{\prime}}\left(r \cdot c_{i}^{\prime \prime}\right)$
4. Output $\boldsymbol{c}^{\prime}=\left(c_{0}^{\prime}, c_{1}^{\prime}\right)$

## Geometry of $K$

$\square$ Use canonical-embedding to associate $u \in K$ with a $\phi(m)$-vector of complex numbers
$\square$ Thinking of $u=u(X)$ as a polynomial, associate $u$ with the vector $\sigma(u)=\left(u\left(\rho^{i}\right)\right)_{i \in Z_{m}^{*}}$
$\square \rho=e^{2 \pi i / m}$, the principal complex $m$ 'th root of unity
■.g., if $u \in Q \subset K$ then $\sigma(u)=(u, u, \ldots, u)$
$\square$ We can talk about the "size of $u$ "
$\square$ say the $l_{2}$ or $l_{\infty}$ norm of $\sigma(u)$
$\square$ For decryption, the "noise element" must be << $q$

## Geometry of $K, K^{\prime}$

$\square K$ can be expressed as a vector-space over $K^{\prime}$
$\square$ Similarly $R$ over $R^{\prime}, R_{q}$ over $R_{q}^{\prime}$, etc.
$\square$ Every $R^{\prime}$-basis $B$ induces a transformation $T_{B}$ : coefficients in $R^{\prime} \mapsto$ element of $R$
$\square$ With canonical embedding on both sides, we have a $C$-linear transformation $T_{B}: C^{\phi(m)} \rightarrow C^{\phi(m)}$
$\square$ We want a "good basis", where $T_{B}$ is "short" and "nearly orthogonal"

## Geometry of $K, K^{\prime}$

$\square$ Lemma 1: There exists $R^{\prime}$-basis $B$ of R for which all the singular values of $T_{B}$ are nearly the same.
$\square$ Specifically $s_{1}(T)=s_{n}(T) \cdot \sqrt{f}$ where $f \leq \frac{\operatorname{rad}(m)}{\operatorname{rad}\left(m^{\prime}\right)}=\Pi$ primes that divide $m$ but not $m^{\prime}$
$\square$ The proof follows techniques from [LPR13], the basis $B$ is essentially a tensor of DFT matrices

## The Trace Function

$\square$ For $u \in K, \operatorname{Tr}(u)=\sum_{i \in Z_{m}^{*}} \sigma(u)_{i} \in Q$
$\square$ By definition: if $u$ is small then so is $\operatorname{Tr}(u)$
$\square \operatorname{Tr}: K \rightarrow Q$ is $Q$-linear
$\square L: K \rightarrow Q$ is $Q$-linear if $\forall u, v \in K, q \in Q$,

$$
L(u)+L(v)=L(u+v) \text { and } L(q \cdot u)=q \cdot L(u)
$$

$\square$ The trace is a "universal" $Q$-linear function:
$\square$ For every $Q$-linear function $L$ there exists $\kappa \in K$ such that $L(u)=\operatorname{Tr}(\kappa \cdot u) \forall u \in K$

## The Trace Function

$\square$ The trace Implies also a $Z$-linear map $\operatorname{Tr}: R \rightarrow Z$, and $Z_{q}$-linear map $\operatorname{Tr}: R_{q} \rightarrow Z_{q}$
$\square$ Every $Z$-linear map $\mathrm{L}: R \rightarrow Z$ can be written as $L(a)=\operatorname{Tr}(\kappa \cdot a)$
$\square$ But $\kappa$ need not be in $R$
$\square$ More on that later

## The Intermediate Trace Function

$\square \operatorname{Tr}_{K / K^{\prime}}: K \rightarrow K^{\prime}$ when $K$ is an extension of $K^{\prime}$
$\square$ Satisfies $\operatorname{Tr}_{K / Q}=\operatorname{Tr}_{K / K^{\prime}} \circ \operatorname{Tr}_{K^{\prime} / Q}$
$\square$ Lemma 2: if $u$ is small then so is $\operatorname{Tr}_{K / K^{\prime}}(u)$
$\square$ Less trivial than for $\operatorname{Tr}_{K / Q}$ but still true
$\square \operatorname{Tr}_{K / K^{\prime}}$ is a "universal" $K^{\prime}$-linear function:
$\square \operatorname{Tr}_{K / K^{\prime}}: K \rightarrow K^{\prime}$ is $K^{\prime}$-linear
$\square$ For every $K^{\prime}$-linear function $L$ there exists $\kappa \in K_{m}$ such that $L(u)=\operatorname{Tr}_{\mathrm{K} / \mathrm{K}^{\prime}}(\kappa \cdot u) \forall u \in K_{m}$
$\square$ Similarly implies $R^{\prime}$-linear map $\operatorname{Tr}_{K / K^{\prime}}: R \rightarrow R^{\prime}$ and $R_{q}^{\prime}$-linear map $\operatorname{Tr}_{K / K^{\prime}}: R_{q} \rightarrow R_{q}^{\prime}$

## Some Complications

$\square$ Often we get $\operatorname{Tr}_{K / K^{\prime}}(R) \subsetneq R^{\prime}$
$\square$ Also for many linear functions we get $L(u)=\operatorname{Tr}_{\mathrm{K} / \mathrm{K}^{\prime}}(\kappa \cdot u)$ where $\kappa$ is not in $R$
$\square$ In our setting this will cause problems when we apply the trace to ciphertext elements
$\square$ That's (one reason) why ciphertexts are not really vectors over $R$
$\square$ Hence the *'s throughout the slides

## The Dual of $R$

$\square$ Instead of $R$, ciphertext are vectors over the dual $R^{\vee}=\{a \in K: \forall r \in R, \operatorname{Tr}(a r) \in Z\}$
$\square \mathrm{R}^{\vee}=\mathrm{R} / \mathrm{t}, \mathrm{R}^{\prime V}=\mathrm{R}^{\prime} / \mathrm{t}^{\prime}$ for some $\mathrm{t} \in R, t^{\prime} \in R^{\prime}$
$\square$ We have $\operatorname{Tr}_{K / K^{\prime}}\left(\mathrm{R}^{\vee}\right)=R^{\prime \vee}$
$\square$ Also every $\mathrm{R}^{\prime}$-linear $L: R^{\vee} \rightarrow R^{\prime V}$ can be written as $L(a)=\operatorname{Tr}_{K / K^{\prime}}(r \cdot a)$ for some $r \in R$
$\square$ In the rest of this talk we ignore this point, and pretend that everything is over $R$

## Prime Splitting

$\square$ The integer 2 splits over $R$ as $2=\prod_{i} \boldsymbol{p}_{i}^{e}$

- $i$ ranges over $G=Z_{m}^{*} /(2)$
$\square \boldsymbol{p}_{i}$ is generated by $\left(2, F_{i}(X)=\prod_{j}\left(X-\zeta_{m}^{i \cdot 2^{j}}\right)\right)$
$\square$ In this talk we assume $e=1$ (i.e., $m$ is odd)
$\square \ell=|G|$ prime ideals, each $R / \boldsymbol{p}_{i} \cong G F\left(2^{d}\right)$
$\square \mathrm{R}_{2}=R /(2) \cong \oplus_{i} R / \boldsymbol{p}_{i} \cong \oplus_{i} G F\left(2^{d}\right)$
$\square$ Using CRT, each $a \in R_{2}$ encodes the vector

$$
(\underbrace{\operatorname{amod} \boldsymbol{p}_{i_{1}}}_{\alpha_{1}}, \ldots, \underbrace{\operatorname{a\operatorname {mod}\boldsymbol {p}_{i_{\ell }}}}_{\alpha_{\ell}}) \in G F\left(2^{d}\right)^{\ell}
$$

## Prime Splitting

$\square$ Similarly 2 splits over $R^{\prime}$ as $2=\prod_{j} \boldsymbol{p}_{j}^{\prime e^{\prime}}$
$\square$ Again we assume $e^{\prime}=1$
$\square$ Using CRT, each $a^{\prime} \in R_{2}^{\prime}$ encodes the vector

$$
(\underbrace{a^{\prime} \bmod \boldsymbol{p}_{j_{1}}^{\prime}}_{\alpha_{1}^{\prime}}, \ldots, \underbrace{a^{\prime} \bmod \boldsymbol{p}_{{j^{\prime}}^{\prime}}^{\prime}}_{\alpha_{\ell}^{\prime}}) \in G F\left(2^{d^{\prime}}\right)^{\ell^{\prime}}
$$

$\square$ When $m^{\prime} \mid m$ then also $d^{\prime}\left|d, \ell^{\prime}\right| \ell$, and each $\boldsymbol{p}_{\boldsymbol{j}}^{\prime}$ split over $R$ as a product of some of the $\boldsymbol{p}_{i}$ 's

## Prime Splitting

$\square$ Example for $m=91, m^{\prime}=7$

## Plaintext-Slot Representation

$\square$ Recall that $R / \boldsymbol{p}_{i} \cong G F\left(2^{d}\right)$ for all the $\boldsymbol{p}_{i}$ 's
$\square$ But the isomorphisms are not unique
$\square$ To fix the isomorphisms:
$\square$ Fix a primitive $m$-th root of unity $\omega \in G F\left(2^{d}\right)$
$\square$ Fix representatives $u_{i} \in Z_{m}^{*}$ for all $i \in Z_{m}^{*} /(2)$
$\square h_{i}: R / \boldsymbol{p}_{i} \rightarrow G F\left(2^{d}\right)$ defined via $h_{i}\left(\zeta_{m}\right)=\omega^{u_{i}}$
$\square$ Same for isomorphisms $R^{\prime} / \boldsymbol{p}_{j}^{\prime} \cong G F\left(2^{d^{\prime}}\right)$

- Define $h_{j}^{\prime}: R^{\prime} / \boldsymbol{p}_{j}^{\prime} \rightarrow G F\left(2^{d^{\prime}}\right)$ by fixing $\rho^{\prime}$ and $u_{j}^{\prime}$

## Plaintext-Slot Representation

$\square$ Making the $h_{i}$ 's and $h_{j}^{\prime}$ 's "consistent"
$\square$ Fix $\omega \in G F\left(2^{d}\right)$ and set $\omega^{\prime}=\rho^{m / m^{\prime}} \in G F\left(2^{d^{\prime}}\right)$
$\square$ Fix $u_{j}^{\prime} \in j \cdot(2) \subset Z_{m^{\prime}}^{*} \forall j$, then $\forall \boldsymbol{p}_{i}$ that lies over $\boldsymbol{p}_{j}^{\prime}$, choose $u_{i} \in i \cdot(2)$ s.t. $u_{i}=u_{j}^{\prime} \bmod m^{\prime}$
$\square$ Fact: if $\boldsymbol{p}_{i}$ lies over $\boldsymbol{p}_{j}^{\prime}$ and $r^{\prime} \in R^{\prime} \subset R$, then

$$
h_{i}\left(r^{\prime} \bmod \boldsymbol{p}_{i}\right)=h_{j}^{\prime}\left(r^{\prime} \bmod \boldsymbol{p}_{j}^{\prime}\right) \in G F\left(2^{d^{\prime}}\right)
$$

$\square$ In words: for a sub-ring plaintext, the slots $\bmod \boldsymbol{p}_{j}^{\prime}$ and all the $\boldsymbol{p}_{i}$ 's lie over it, hold the same value

## Plaintext-Slot Representation

$\square$ Lemma 3: $\forall$ collection of $G F\left(2^{d \prime}\right)$-linear functions $\left\{L_{j}: G F\left(2^{d}\right)^{\frac{\ell}{\ell^{\prime}}} \rightarrow G F\left(2^{d^{\prime}}\right)\right\}_{j \in Z_{m^{\prime}}^{*} / 2}$
$\exists$ a unique $R_{2}^{\prime}$-linear function $L: R_{2} \rightarrow R_{2}^{\prime}$ s.t.

$$
h_{j}^{\prime}\left(a^{\prime} \bmod \boldsymbol{p}_{j}^{\prime}\right)=L_{j}\left(\left(h_{i}\left(a \bmod \boldsymbol{p}_{i}\right)_{i}\right)\right)
$$

holds $\forall a \in R_{2}$ and $a^{\prime}=L(a)$, and $\forall j$
$\square$ The $i$ 's range over all the $\boldsymbol{p}_{i}$ 's that lie over $\boldsymbol{p}_{j}^{\prime}$

## Illustration of Lemma 3

$$
\boldsymbol{p}_{1} \boldsymbol{p}_{15} \boldsymbol{p}_{22}
$$

$\square \exists L: R_{2} \rightarrow R_{2}^{\prime}$ s.t. $\forall a \in R_{2}$ and $a^{\prime}=L(a) \in R_{2}^{\prime}$
$\square h_{1}^{\prime}\left(a^{\prime}\right)=L_{1}\left(h_{1}(a), h_{15}(a), h_{22}(a)\right)$
$\square h_{3}^{\prime}\left(a^{\prime}\right)=L_{2}\left(h_{3}(a), h_{17}(a), h_{31}(a)\right)$
$\square$ Can express $L(a)=\operatorname{Tr}_{K / K^{\prime}}(r \cdot a)$ for some $r \in R_{2}^{*}$

* Not exactly

## Step 1, Key Switching

$\square$ Let $\boldsymbol{s} \in R_{q}^{2}, \boldsymbol{s}^{\prime} \in R_{q}^{\prime 2} \subset R_{q}^{2}$ (chosen at keygen)
$\square$ Publish a key-switching matrix $W\left[\boldsymbol{s} \rightarrow \boldsymbol{s}^{\prime}\right]$
$\square$ Given ctxt $\boldsymbol{c}$ wrt $\boldsymbol{s}$, use W to get $\boldsymbol{c}^{\prime \prime}$ wrt $\boldsymbol{s}^{\prime}$
$\square$ Just plain key-switching in the big ring
$\square \boldsymbol{c}^{\prime \prime}$ still over the big ring, but wrt a sub-ring key
$\square \boldsymbol{c}^{\prime \prime}$ encrypts the same $R_{2}$-element as $\boldsymbol{c}$

## Security of Key-Swicthing

$\square$ Security of usual big-ring key-switching relies on the secret $\boldsymbol{s}^{\prime}$ being drawn from $R_{q}$

- Then $W$ constrains only LWE-instance over $R_{q}$
$\square$ What can we say when it is drawn from $R_{q}^{\prime}$ ?
$\square$ We devise LWE instances over $R_{q}$ with secret from $R_{q}^{\prime}$, with security relying on LWE in $R_{q}^{\prime}$
$\square$ Instead of one small error element in $R_{q}$, choose many small elements in $R_{q}^{\prime}$, use an $R_{q}^{\prime}$-basis of $R_{q}$ to combine them into a single error element in $R_{q}$

## $R_{q}$-LWE With Secret in $R_{q}^{\prime}$

$\square$ Let $B=\left(\beta_{1}, \ldots, \beta_{n}\right)$ be any $R_{q}^{\prime}$-basis of $R_{q}$
$\square$ Given the LWE secret $s^{\prime} \in R_{q}^{\prime} \subset R_{q}$
$\square$ Choose uniform $a \leftarrow R_{q}$ and small $e_{1}^{\prime}, \ldots, e_{n}^{\prime} \leftarrow R_{q}^{\prime}$
$\square$ Set $e=\sum_{i} e_{i}^{\prime} \beta_{i} \in R_{q}$ and output ( $\left.a, b=a s^{\prime}+e\right)$
$\square$ If the basis B is "good" (short, orthogonal) then $e$ is not much larger than the $e_{i}^{\prime \text { 's }}$
$\square$ This is where we use Lemma 1 ( $\exists$ good basis)

## $R_{q}$-LWE With Secret in $R_{q}^{\prime}$

$\square$ Theorem: If decision-LWE is hard in $R_{q}^{\prime}$, then $(a, b)$ is indistinguishable from uniform in $R_{q}^{2}$
$\square$ Proof:
$\square$ We can consider $a=\sum_{i} a_{i}^{\prime} \beta_{i}$ for uniform $a_{i}^{\prime} \leftarrow R_{q}^{\prime}$

- Induces the same uniform distribution on $a$
$\square$ Then we would get $b=\sum_{i}\left(a_{i}^{\prime} s^{\prime}+e_{i}^{\prime}\right) \beta_{i}$.
- If the ( $a_{i}^{\prime} s^{\prime}+e_{i}^{\prime}$ ) were uniform in $R_{q}^{\prime}$, then $b$ would be uniform in $R_{q}$.

## Steps 2,3: Ring Switching

$\square \boldsymbol{c}^{\prime \prime}$ encrypts $a \in R_{2}$ wrt $\boldsymbol{s}^{\prime}$
$\square a$ encodes a vector $\boldsymbol{\alpha}=\left(\alpha_{i}\right)_{i} \in G F\left(2^{d}\right)^{\ell}$
$\square$ We view it as $\boldsymbol{\alpha}=\left(\boldsymbol{\alpha}_{1}, \ldots, \boldsymbol{\alpha}_{\ell^{\prime}}\right) \in\left(G F\left(2^{d}\right)^{\ell / \ell \prime}\right)^{\ell^{\prime}}$
$\square \ell^{\prime}$ target functions, $L_{j}: G F\left(2^{d}\right)^{\ell / \ell^{\prime}} \rightarrow G F\left(2^{d^{\prime}}\right)$
$\square$ Want small-ring ciphertext $\boldsymbol{c}^{\prime}$ encrypting $a \in R_{2}^{\prime}$ that encodes $\boldsymbol{\alpha}^{\prime}=\left(\alpha_{1}^{\prime}, \ldots, \alpha_{\ell^{\prime}}^{\prime}\right) \in G F\left(2^{d^{\prime}}\right)^{\prime}$
$\square$ For each $j, \alpha_{j}^{\prime}=L_{j}\left(\boldsymbol{\alpha}_{j}\right)$

## Steps 2,3: Ring Switching

$\square$ By Lemma 2, $\exists L: R_{2} \rightarrow R_{2}^{\prime}$ that induces the $L_{j}$ 's
$\square$ Expressed as $L(a)=T r_{K / K^{\prime}}(r \cdot a)$ for $r \in R_{2}^{\prime *}$
$\square$ We identify $r$ with a short representative in $R^{\prime}$
■ One must exists since 2 is "short"

- Thus identify $L$ with $L(a)=\operatorname{Tr}_{K / K^{\prime}}(r \cdot a)$ over $R$
$\square$ Further identify $r$ as a representative of $r \in R_{q}^{\prime}$
$\square$ Apply the trace, $c_{i}^{\prime}=\operatorname{Tr}_{K / K^{\prime}}\left(r \cdot c_{i}^{\prime \prime}\right)$
$\square$ Recall that $\boldsymbol{c}^{\prime \prime}$ is valid wrt $\boldsymbol{s}^{\prime} \in R_{q}^{\prime} \subset R_{q}$

## Correctness

$\square \operatorname{Recall}\left\langle s^{\prime}, c^{\prime \prime}\right\rangle=k \cdot q+a \cdot \frac{q}{2}+e$ over $K$
$\square$ For some $k, e \in R$ (with $e$ small) and $\mathbf{s}^{\prime}$ over $R^{\prime}$
$\square$ Thus we have the equalities (over $K$ ):

$$
\begin{aligned}
& \quad\left\langle s^{\prime}, c^{\prime}\right\rangle=\left\langle s^{\prime}, T r_{K / K^{\prime}}\left(r \cdot c^{\prime \prime}\right)\right\rangle=T r_{K / K^{\prime}}\left(r \cdot\left\langle s^{\prime}, c^{\prime \prime}\right\rangle\right) \\
& =L\left(q \cdot k+a \cdot \frac{q}{2}+e\right)=L(k) \cdot q+L(a) \cdot \frac{q}{2}+L(e) \\
& \quad=k^{\prime \prime} \cdot q+a^{\prime} \cdot \frac{q}{2}+e^{\prime \prime}
\end{aligned}
$$

$\square a^{\prime}$ encodes the $\alpha_{j}^{\prime \prime}$ 's that we want

## Correctness

- We have $\left\langle s^{\prime}, c^{\prime}\right\rangle=k^{\prime} \cdot q+a^{\prime} \cdot \frac{q}{2}+e^{\prime}$
$\square$ This looks like a valid encryption of $a^{\prime}$
$\square$ It remains to show that $e^{\prime}$ is short
$\square e^{\prime}=L(e)=T r_{K / K^{\prime}}(r \cdot e)$
$\square e$ is short (from the input), $r$ is short (reduced mod 2)
$\square$ So $r \cdot e$ is short
$\square$ By Lemma 3 also $\operatorname{Tr}_{K / K^{\prime}}(r \cdot e)$ is short

## Conclusions

$\square$ We have a general ring-switching technique
$\square$ Converts $\boldsymbol{c}$ over $R_{m}$ to $\boldsymbol{c}^{\prime}$ over $R_{m^{\prime}}$ for $m^{\prime} \mid m$
$\square$ The plaintext slots in $\boldsymbol{c}^{\prime}$ can contain any linear functions of the slots in $\boldsymbol{c}$

- A $\boldsymbol{c}^{\prime}$-slot is a function of the $\boldsymbol{c}$-slots that lie above it
$\square$ We may choose projection functions to have $\boldsymbol{c}^{\prime}$ contain subset of the slots of $\boldsymbol{c}$
$\square$ Lets us to speed up computation by switching to a smaller ring

## Epilog: The [AP 13] Work

Alperin-Sheriff \& Peikert described a clever use of ring-switching for efficient homomorphic computation of DFT-like transformations:

1. Decompose it to an FFT-like network of "local" linear functions
2. Use ring-switching for each level
3. Then switch back up before the next level

Yields fastest bootstrapping procedure to date
